

owner's handover guide

making kula yours.

Written for a smart non-technical owner — every step is "go to this website, click this button." No coding required. Budget a relaxed afternoon, and pull Aleks in for the two steps marked 🤝 (they touch his accounts).

Where things stand today: the finished marketplace is live at yogamp.netlify.app, running on Aleks's accounts with Stripe in test mode (fake money). Your original site at kula-marketplace.com keeps running untouched until the very last step, when the domain switches over to the new one.

◦ what you're taking ownership of

kula is four services working together, plus the code that ties them into one website:

Service	What it does	Cost
GitHub	Stores the code. Netlify watches it and republishes the site whenever the code changes.	Free
Supabase	The database — every user account, listing, order, and uploaded file lives here.	Free to start
Stripe	Moves the money. Buyers pay; Stripe sends instructors their share and deposits your fee to your bank. Also handles instructors' identity checks and tax forms.	~2.9% + 30¢ per sale, plus \$2/mo per instructor who got a payout that month
Netlify	Publishes the website to the internet at your domain.	Free to start

Once the swap below is done, **every one of these runs under your accounts** — your logins, your dashboards, your money. Nothing stays attached to Aleks.

1 create your four accounts

~15 min

GitHub first — it can log you into two of the others.

- 1 Go to **github.com** → Sign up. Use your everyday email; pick a username (semi-public — `yourname` or `kuLamarketplace` is fine). Free plan.
- 2 **supabase.com** → Start your project → **Continue with GitHub** → authorize.
- 3 **netlify.com** → Sign up → **Sign up with GitHub** → authorize.
- 4 **stripe.com** → Sign up with your email. It asks about your business — answer as yourself (sole proprietor is fine to start). This is the one account where real identity matters: it's a money account. You do *not* need to "activate" yet — everything below works in test mode.

2 🤝 move the code into your GitHub

~5 min, with Aleks

- 1 *Aleks*: on the repo page → Settings → scroll to **Danger Zone** → **Transfer ownership** → your GitHub username.
- 2 *You*: accept the email invitation GitHub sends.
- 3 The code now lives at `github.com/YOUR-USERNAME/kula-marketplace`. That's the master copy of your site.

3 your own database (Supabase)

~10 min

- 1 Supabase dashboard → **New project**. Name: `kula-marketplace`. Database password: click **Generate** and save it in your password manager. Region: East US. Wait ~2 minutes.
- 2 Left sidebar → **SQL Editor** → New query.
- 3 Open the file `supabase/migrations/001_init.sql` from the code (on GitHub: browse to `supabase` → `migrations` → click the file → the copy icon grabs the whole thing).
- 4 Paste into the editor → **Run**. "Success. No rows returned" = your entire database now exists: accounts, listings, orders, file storage, and all the security rules.
- 5 Collect your keys (used in Part 4) from **Project Settings (gear)** → **API** — keep this tab open: the **Project URL**, the **anon / publishable** key, and the **service_role / secret** key.

⚠ **The service_role key is the master key.** Treat it like a bank password — the only place you ever paste it is Netlify's environment-variables page.

While testing: Authentication → Sign In / Providers → Email → toggle **"Confirm email" OFF** (and Save) so fake signups don't wait on confirmation links. Flip it back ON at go-live (Part 8).

4 publish the site (Netlify)

~10 min

- 1 Netlify → **Add new site** → **Import an existing project** → **GitHub** → choose `kula-marketplace`. Don't change any build settings — Netlify recognizes the site type automatically.
- 2 Find **Environment variables** (during import, or after under Site configuration). Choose **Add key/value pairs** and enter the six below — names must match EXACTLY. Leave "secret" unchecked and scopes/contexts at their defaults.
- 3 **Deploy**. Netlify assigns your address, like `https://something.netlify.app` — go back and fill that into `NEXT_PUBLIC_SITE_URL`, then **Deploys** → **Trigger deploy**.

Name	Value comes from
NEXT_PUBLIC_SUPABASE_URL	Supabase → Project URL
NEXT_PUBLIC_SUPABASE_ANON_KEY	Supabase → anon / publishable key
SUPABASE_SERVICE_ROLE_KEY	Supabase → service_role / secret key
STRIPE_SECRET_KEY	Stripe → Developers → API keys → Secret key (starts <code>sk_test_</code> while testing)
STRIPE_WEBHOOK_SECRET	Part 5 — come back and fill it in, then redeploy
NEXT_PUBLIC_SITE_URL	your site's address, e.g. <code>https://something.netlify.app</code>

5 connect the money pipe (Stripe webhook)

~5 min

This is how Stripe tells your site "payment succeeded — release the file." Without it, purchases never complete.

- 1 Stripe → **Developers** → **Webhooks** (Stripe may call it "Event destinations") → **Add endpoint**.
- 2 Scope: **Your account**. Endpoint URL: `https://YOUR-SITE-ADDRESS/api/stripe/webhook`
- 3 Select exactly these four events (search for them): `checkout.session.completed` , `checkout.session.async_payment_succeeded` , `checkout.session.expired` , `charge.refunded`
- 4 Create it → open it → **Reveal** the Signing secret (`whsec_...`) → paste into Netlify as `STRIPE_WEBHOOK_SECRET` → trigger another deploy.

6 crown yourself admin

~2 min

- 1 On your live site: **Sign up** with your email (either role — doesn't matter).
- 2 Supabase → SQL Editor → New query → paste this with your email, then **Run**:

```
update public.profiles set role = 'admin' where email = 'you@example.com';
```

Log out and back in on the site. Your dashboard is now the admin panel: set the platform fee, see every order and your fee revenue, suspend listings, and change anyone's role — no SQL ever needed again.

7 test drive with fake money

~10 min

- 1 Sign up (second email, or gmail +tags like `you+seller@gmail.com`) as a **seller** → dashboard → **connect stripe** → fill onboarding with fake info: phone `000-000-0000` , code `000-000` , use the test bank it offers.
- 2 Post a listing with any PDF, price it \$20, publish.
- 3 In a private/incognito window sign up as a **buyer** and buy it with card `4242 4242 4242 4242` , any future date, any CVC.
- 4 Confirm: checkout showed your platform fee as its own line · the download worked · the order and your fee appear in your admin dashboard.

8 go live — real sales

when you're ready

- 1 **Stripe activation:** complete it with your real identity/bank details (the dashboard walks you through). Flip the test/live toggle and copy the **live** Secret key (`sk_live_...`) into Netlify, replacing the test one.
- 2 **Live webhook:** while in live mode, create a second endpoint (same URL, same four events — live mode has its own signing secret) and update `STRIPE_WEBHOOK_SECRET` . Redeploy.
- 3 **Supabase:** Authentication → Email → turn "**Confirm email**" **back ON** — real users should verify their addresses.
- 4 🍷 **The domain switch:** Netlify → Domain management → add `kula-marketplace.com` and follow its DNS instructions (the DNS settings live wherever the domain was bought — do this one with Aleks). Then set `NEXT_PUBLIC_SITE_URL` to `https://kula-marketplace.com` and redeploy. *This is the moment the old Replit site retires and the new kula takes its address.*
- 5 **Legal pages before promoting it:** Terms of Service, refund policy, and a seller agreement (lawyer-reviewed template is fine). Note: payment disputes are charged to the seller's balance — sellers should agree to that in writing.

✦ afterward

What happens to Aleks's version? His Supabase/Stripe/Netlify projects were only ever the test environment. Nothing needs to move — your projects start clean, and once you're live he simply deletes his.

If this happens later...	Do this
Purchases stop completing	9 times out of 10 it's the webhook: Stripe → Webhooks → your endpoint shows red failed attempts. Check <code>STRIPE_WEBHOOK_SECRET</code> in Netlify matches the endpoint's signing secret.
Site won't build after a code change	Netlify → Deploys → open the failed deploy to see the log, or retry the previous good one.
You want a code change	The code is yours on GitHub. Any developer, Aleks, or an AI coding tool can work on it — there's a <code>CLAUDE.md</code> briefing file in the repo for exactly that.
